## **Abstract**

### **Background:**

Women suffering from first onset postpartum mental disorders (PPMD) have a highly-elevated risk of suicide. The current study aimed to: (1) describe the risk of self-harm among women with PPMD and (2) investigate the extent to which self-harm is associated with later suicide.

### **Methods:**

We conducted a register-based cohort study linking national Danish registers. This identified women with any recorded first inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to their first child. The main outcome of interest was defined as first hospital-registered episode of self-harm. Our cohort consisted of 1,202,292 women representing 24,053,543 person-years at risk.

### **Results:**

Among 1554 women with severe first onset PPMD, 64 had a first-ever hospital record of self-harm. Women with PPMD had a hazard ratio (HR) for self-harm of 6.2 (95% CI: 4.9-8.0), compared to mothers without mental disorders; but self-harm risk was lower in PPMD women compared to mothers with non-postpartum mental disorders [HR: 10.1, (95% CI 9.6-10.5)] and childless women with mental disorders [HR: 9.3 (95% CI 8.9-9.7)]. Women with PPMD and records of self-harm had significantly greater risk for later suicide compared with all other groups of women in the cohort.

### **Conclusions:**

Women with PPMD had a high risk of self harm, although lower than risks observed in other psychiatric patients. However, PPMD women who had self-harmed constituted a vulnerable group at significantly increased risk of later suicide.

## Background

The first twelve months after childbirth is a vulnerable time for any new mother, involving rapid biological, social and emotional changes.(Howard et al., 2014, Jones et al., 2014, Meltzer-Brody et al., 2018) The incidence of new onset mental disorder is high, particularly in the first three months postpartum. (Wisner et al., 2013, Jones et al., 2014) Recent evidence further indicates variations in incidence, as moderate postpartum mental disorder (when defined as disorders treated with antidepressants and/or antipsychotics) occurs in 7.72 cases per 1000 births, and moderate-severe disorders (when defined as disorders requiring psychiatric outpatient treatment) in 1.63 cases per 1000. In comparison, the most severe episodes requiring specialized inpatient psychiatric treatment, occur in 0.64 cases per 1000 births.(Munk-Olsen et al., 2016)

Negative mental health outcomes have been observed among women suffering from postpartum mental disorders, including a concerning highly elevated risk of suicide within the first year after initial diagnosis. (Johannsen et al., 2016, Khalifeh et al., 2016, Appleby et al., 1998) This has been confirmed through inquiries into maternal deaths in the UK and other high-income countries which identified suicides as one of the leading causes of death among new mothers. (Lewis, 2001, Lewis, 2004, Thornton et al., 2013)

Prior history of self-harm is an established and significant risk factor for later suicide amongst the general population. (Cavanagh et al., 2003, Carroll et al., 2014, Olfson et al., 2017, Runeson et al., 2016) One small case control study of female emergency department attendees showed that the rate of self-harm in the postpartum period was lower than expected given the high

incidence of new onset mental disorder on the postpartum period. (Appleby and Turnbull, 1995)

However, to our knowledge no previous study has investigated and quantified the risk of self-harm specifically among women with first onset of postpartum mental disorder, or whether self-harm is associated with later suicide in this population.

Consequently, the aims of this study were:

- To describe the risk of self-harm among women with a diagnosis of first-onset postpartum mental disorder compared to other groups of women from the background population (both mothers and childless women, with and without non-postpartum onset of mental disorders).
- To investigate the extent to which self-harm in women with a diagnosis of first onset postpartum mental disorder is associated with later suicide.

## Methods

### Study design and population

In order to investigate our aim we conducted an epidemiological register-based cohort study using Danish population data.

For our main analysis we included all women born in Denmark on January 1<sup>st</sup> 1963 or later. Follow-up started at the women's 15<sup>th</sup> birthday and was completed at date of first hospital-registered self-harm episode; date of death, emigration, or December 31<sup>st</sup> 2016, whichever came first. This allowed a maximum follow-up period of 39 years in the cohort comprising a total of 1,202,292 women.

The main exposure variable was first onset of moderate-severe postpartum mental disorder. Moderate-severe postpartum mental disorder was defined as a woman experiencing any *first* inpatient or outpatient contact with a psychiatric facility within 90 days after giving birth to her first live-born child, and is referred to as “postpartum mental disorder” across this paper. In defining contacts and treatments at psychiatric treatment facilities we included all diagnostic codes in the F-chapter of mental and behavioral disorders in ICD-10 (F00-F99) and the corresponding diagnostic codes in ICD-8 (290.xx-315.xx). (Pedersen et al., 2014) By defining postpartum mental disorders as those occurring within a restricted interval of three months after giving birth, we assumed that childbirth was the specific triggering factor causing the onset of the disorder in the affected women.

The main outcome of interest was any first self-harm leading to a hospital-registered episode, as a recorded inpatient or outpatient contact of self-harm at either medical or psychiatric hospitals. This was defined by the women included in the cohort fulfilling at least **one** of the following 5 criteria (Helweg-Larsen et al., 2005, Gasse et al., 2018):

1. “suicide attempt” as contact reason within the register,
2. an ICD-8 diagnosis within diagnostic codes: E9500-E9599,
3. a contact with a main diagnosis within the ICD-10 F-chapter (mental disorder) and a secondary diagnosis of poisoning (ICD-10: T36-T50 and T52-T60) or lesions at the forearm, wrist, or hand (ICD-10: S51, S55, S59, S61, S65, and S69),
4. a main diagnosis of poisoning with weak analgesics, epileptic drugs, or carbon monoxide (ICD-10: T39, T42, T43, and T58) or
5. a diagnosis of suicide attempt or deliberate self-harm (ICD-10: X60-X84).

Please note, that we considered only the **first** recorded episode of self-harm from the list above.

## **Data sources**

Data for the study was based on a total of four national Danish registers:

1. The Danish Civil Registration System (CRS)(Pedersen, 2011) was initiated in 1968 and holds information on every individual in Denmark that has a unique identification number (CRS number). This identification number allows linkage of information on individuals within and between registries. We included data on CRS number, gender, date of birth, vital status, data on all children and the women’s parents from this register.
2. The Danish Psychiatric Central Register (PCR)(Mors et al., 2011) includes data on all admissions to psychiatric inpatient facilities in Denmark since it was established in 1969.

Information on all outpatient contacts to psychiatric facilities was added to the register from 1995. Therefore, we were able to identify information on psychiatric inpatient and outpatient contacts for the women included in the cohort. Additionally, we included data on any psychiatric contacts the women's parents might have had from 1969 and onwards, allowing us to adjust our analyses for confounding of family history of mental illness.

3. The Danish National Patient Register (NPR)(Lynge et al., 2011) provided data on all medical inpatient contacts to hospitals in Denmark from January 1<sup>st</sup> 1977 and onward. Information on outpatient contacts was added to the registry from January 1<sup>st</sup> 1995. This register allowed us to identify hospital records of self-harm among the women included in our cohort. Therefore, starting inclusion of women born from 1963 and onwards ensured complete follow-up information on the outcome of interest from the age of 15 years (start of follow-up) in 1978 for all women in the cohort. Furthermore, this register allowed us to draw information on parental self-harm and thereby the possibility to adjust for family history of self-harm in at least one parent.

4. The Danish Register of Causes of Death (Helweg-Larsen, 2011) was computerized in 1970 and provides data on all causes of death among Danish citizens dying in Denmark. This register contained the data necessary to define specifically suicides (ICD-10: X60-X84; ICD-8: E950-E959) as cause of death among the women in our cohort as well as parental suicides. Hereby, we were able to adjust our analyses for suicide of at least one parent.

Until December 31<sup>st</sup> 1993 the diagnostic system used in Denmark was the ICD-8 (Sundhedsstyrelsen, 1976), and from January 1<sup>st</sup> 1994 the ICD-10 system was introduced.

### **Definition of reference and comparison groups**

For our main analysis, the defined reference group consisted of mothers from the healthy background population, giving birth to their first child with no records of a psychiatric diagnosis either before or after childbirth.

In additional analyses, we compared the risk of self-harm among women with postpartum mental disorders to other groups of women with varying status of mental health and motherhood. This addition of further comparison groups was done to examine how mental health and motherhood influences risk of both self-harm and suicide.(Appleby and Turnbull, 1995, Johannsen et al., 2016) Consequently, all women in the cohort were classified into a total of five groups in a time-dependent variable depending on their mental health and parity status throughout the follow-up period:

1. Mothers with postpartum mental disorders. This was defined as any first inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to their first child.
2. Mothers without mental disorders (reference group). This consisted of women with no registered history of contact to a psychiatric facility and who have given birth to at least one child.
3. Mothers with a diagnosis of mental disorder occurring outside the postpartum period. This was defined as women who have given birth to their first child and have a first inpatient or outpatient psychiatric contact outside the 90-day postpartum period (either before or after).
4. Childless women with mental disorders. This consisted of women with any first inpatient or outpatient contact to a psychiatric facility without any record of childbirth.

5. Childless women without mental disorders. This consisted of women without any record of contact to a psychiatric facility and without any record of childbirth.

When defining group 1 (mothers with postpartum mental disorders) as the first ever inpatient or outpatient contact within the short time-period of 90 days after giving birth, we assumed that childbirth was the specific trigger causing the psychiatric episode.(Munk-Olsen et al., 2014, Munk-Olsen et al., 2006)

Please note that implementation of these five time-dependent variables enabled dynamic classifications were the women could transition between groups and contribute person-time to different comparison groups throughout the course of follow-up-time depending on when and if they had their first psychiatric contact and its possible relation to the potential birth of a first-born child. (For further description see appendix 1)Furthermore, our analysis built on the assumption that the specific dates of first psychiatric inpatient or outpatient contact and childbirth mark a change in group membership category. As a consequence, any potential prodromal phase leading up to the onset of mental disorders are not taken in to account, as is the case with any study design including time-dependent co-variates. Further, we conducted a sensitivity analysis of our main analysis expanding the onset of postpartum mental disorder from the first 3months (90 days) after giving birth to 6 months postpartum (180 days).

### **Statistical Analysis**

We conducted survival analyses with hazard ratios as the main outcome measure, using Cox regression in Stata, version 13 (StataCorp, College Station, Tex.). Age was chosen as the underlying time in all analyses as is customary in these types of studies with register-based Cox

regression. Further, all analyses were adjusted for calendar time as a time-dependent variable. Further, we adjusted for the time-dependent variables of family history of mental disorder, parental self-harm and parental suicide defined as any psychiatric inpatient or outpatient contact, any hospital recorded episode of self-harm or death categorized as suicide among either of the women's parents.

### **Analysis of short-term versus long-term risk of self-harm**

In order to specifically study the short versus the long term risk of self-harm following a diagnosis of postpartum mental disorder, we conducted a subanalysis calculating specific hazard ratios for the risk of receiving a first-ever hospital record for self-harm up to 12 months after first inpatient or outpatient contact to a psychiatric facility as well as first-ever self-harm episode beyond the first 12 months after diagnosis. These hazard ratios were compared to the risk of first-ever self-harm episode of mothers without any record of self-harm in the entire time-period from 1963-2016.

### **Analysis of suicide risk following a self-harm episode**

In order to investigate our secondary aim of describing the risk of suicide among those with a history of self-harm, we conducted a sub-analysis on the sub-cohort of women registered with an episode of self-harm throughout the follow-up period. Here each woman was followed from the date of their first hospital-registered self-harm until date of suicide, date of death by other causes or December 2016, whichever came first.

## Results

A total of 1,202,292 Danish women were included in our study cohort representing 24,053,543 person-years at risk throughout the entire follow-up period. We identified 1,554 mothers with first onset postpartum mental disorders (Table 1) i.e. experiencing first psychiatric outpatient or inpatient contact to a psychiatric facility within 90 days after giving birth to their first child.

Among the mothers with postpartum mental disorders we identified 64 women who had a first-ever hospital record of self-harm following their diagnosis.

Among the 64 women with first onset postpartum mental disorders and a hospital record of self-harm following their diagnosis the majority were diagnosed with anxiety or stress-related mental disorders (n=20, 31.3%) or affective mood disorders (n=18, 28.1%) in the postpartum period. Six (9.4%) women had a schizophrenia or schizotypal disorder, and 5 (7.81%) women had diagnoses of mental and behavioral disorders associated with the puerperium. The remaining 15 (23.43%) women were recorded having other diagnoses including personality disorders.

Table 1 further shows the characteristics of the cohort in term of agedistribution, parental history of mental illness, self-harm and/or suicide presented as person-years at risk and number of self-harm cases.

### Risk of self-harm

The adjusted hazard ratio (HR) of self-harm was 6.2 (95% CI: 4.9-8.0) i.e. the risk was higher in women with first onset postpartum mental disorders, compared to mothers from the healthy general population without mental disorders. However, when compared to both childless women and mothers with a mental disorder outside the postpartum period, women with postpartum

mental disorders had a lower risk of self-harm. More precisely, the risks for self-harm were: HR 10.1 (95% CI: 9.6-10.5) for mothers with mental disorders occurring outside the postpartum period and 9.3 (95% CI: 8.9-9.7) in childless women with mental disorders (see Table 2). In our sensitivity analysis with onset of postpartum mental disorders expanded to 6 months (180 days) after childbirth we found almost identical results. (Please see appendix 2)

### **Timing of self-harm after diagnosis**

Table 3 shows the short-term and long-term risk of self-harm among women with postpartum mental disorders compared to the lifetime risk of self-harm in mothers from the background population without mental disorders. Overall, risk of self-harm was highest in close proximity to the time of diagnoses – the HR of self-harm within the first 12 months after postpartum mental disorder diagnosis was 13.5 (95% CI 8.4-21.7) among women with postpartum mental disorders (n=17 women). After the initial 12 months this risk decreased: HR 5.2 (95% CI 3.9-6.9) (n=47 women).

### **Risk of recurrent episodes of self-harm and suicide**

Thirty-three (51.5%) of the 64 cases of self-harm in women with postpartum mental disorder had at least one hospital record of subsequent self-harm during the follow-up period. 48.4% of the women self-harmed more than once, with 8 individuals (12.5%) having more than 4 hospital registered episodes of self-harm (results not shown).

The HR for suicide after an episode of self-harm in women with first onset postpartum mental disorders compared to mothers without a mental disorders was 8.7 (95% CI: 3.5-21.7) (see Table

4). Furthermore, women with postpartum mental disorders had a significantly higher risk of suicide than the other groups of women with mental disorders - both when compared with mothers with non-postpartum mental disorders (HR 2.7; 95% CI: 1.9-3.7; p-value= 0.0104) and childless women with mental disorders (HR 2.8; 95% CI: 2.1-3.8; p-value= 0.0125).

## **Discussion**

Using register data covering the entire Danish population, we found that women with first-onset postpartum mental disorders are at increased risk of self-harm compared with mothers from the healthy background population. Nevertheless, their risk of self-harm was the lowest among all comparison groups of women with mental disorders – both mothers and non-mothers.

Importantly, we further found that a record of self-harm among women with postpartum mental disorders was associated with the significantly highest risk of later suicide among all the comparison groups.

### **Risk of self-harm in mothers with postpartum mental disorders**

This present study is, the first population-based study to describe the incidence of self-harm among women with first-onset postpartum mental disorders. Primiparous women experiencing postpartum mental disorders within the first 90 days postpartum had an increased risk of a hospital contact due to self-harm, which was approximately 6 times higher than in mothers without mental disorders.

Previous studies have reported increased rates of suicidal ideation among women in the postpartum period,(Lindahl et al., 2005, Wisner et al., 2013) using data from a specific question relating to thoughts of self-harm (question 10) in the Edinburgh Postnatal Depression Scale (EPDS) in women with postpartum mental disorders.(Cox et al., 1987, Lindahl et al., 2005, Wisner et al., 2013) While the EPDS is a highly valid tool in identifying high risk patients for postpartum depression and questions regarding suicidal behavior (thoughts of self-harm and/or suicide) are included (Adouard et al., 2005, Rubertsson et al., 2011), for this study we used a much more specific instrument in evaluating suicidal behavior as we were able to identify

women who had actually acted on potential self-harming impulses. One previous study has described an increased risk of self-harm among pregnant women with pre-existing mental disorders. (Taylor et al., 2016) However, so far no studies have described the extent to which women with first onset postpartum mental disorders act on such thoughts of self-harm.

### **Risk of self-harm compared to other groups of psychiatric patients**

Motherhood in general appears to be a protective factor in terms of reducing self-harm, suicidal ideation and mortality.(Johannsen et al., 2016, Appleby and Turnbull, 1995, Lysell et al., 2018) However, mental disorders constitute a well-established major risk factor for self-harm(Christiansen et al., 2013) and may therefore add to the complexity of the risk evaluation for suicidal and self-harming behavior in new mothers. In this present study, we considered various states of mental ill-health (absent, postpartum, non-postpartum) and also motherhood (mothers, non-mothers), by using multiple comparison groups of women drawn from the background population. The risk of self-harm in women with postpartum mental disorders was increased (HR 6.2; 95% CI: 4.9-8.0) when compared to mothers without any record of psychiatric admissions. While our results confirmed a generally increased risk of self-harm in the three groups of women with mental disorders (both mothers and childless women), in our more detailed analyses we found that women with a diagnosis of postpartum mental disorder had the lowest risk of hospital recorded contacts due to self-harm involving hospital contact when compared to groups of women with alternate onset of mental disorders (both mothers and childless women). These results indicate important clinical variations in self-harm risks, related to both mental health and motherhood.

### **Self-harm as risk factor for later suicide in women with postpartum mental disorders**

Self-harm is one of the leading risk factors for later suicide. (Olfson et al., 2017, Runeson et al., 2016, Carroll et al., 2014, Cavanagh et al., 2003) This was also confirmed in the present study, where women suffering from postpartum mental disorders with records of self-harm had significantly highest risk of later suicide amongst all comparison groups (HR 8.7; 95% CI: 3.5-21.7), including women with onset of mental disorders at alternate time points (both mothers and childless women). These results add to the already worrying evidence suggesting that women with the most severe forms of mental disorders following childbirth are at significant increased risk of dying by suicide, especially within the first year after diagnosis. (Johannsen et al., 2016, Appleby et al., 1998, Khalifeh et al., 2016, Lysell et al., 2018) An additional aspect is that women who do exhibit suicidal behavior in the postpartum period are more likely to use violent methods when dying by suicide and thereby possibly indicating a higher suicidal intent. (Lindahl et al., 2005, Appleby, 1991, Esscher et al., 2016) Unfortunately, we were not able to stratify our analysis on violent vs. non-violent methods of self-harm and/or suicide due to lack of statistical power.

### **Clinical perspectives**

Our results demonstrate that women with postpartum mental disorders who have a hospital record of self-harm following their psychiatric diagnosis, constitute a selected group of high-risk patients for later suicide. These results must however be considered alongside the observation that absolute number of women with first onset postpartum mental disorders who self-harm and commit suicide are low (five women in the present study). Regardless, each single case

represents a significant increased relative risk among this specific group of vulnerable new mothers, which is clinically significant.

Our results also show that the first year following initial diagnosis carries the highest risk of self-harm for women with postpartum mental disorders (see Table 3), which indicates a particular at-risk period. Hence, goals for future research projects should be aimed at tools for early identification of women: (1) who will develop first onset postpartum mental disorders following childbirth and (2) who are at risk of self-harm and suicidal behaviors, in order to identify them before they act on such impulses.

### **Strengths and limitations**

This study was based on information from the national Danish health registers. In Denmark there is free and equal access both to medical and mental health care and every individual treated is registered by CPR-number.(Pedersen, 2011) This way we were able to ensure a representative study population, and thus minimise selection bias.

We aimed to investigate types of postpartum mental disorders, and consequently defined these as disorders requiring inpatient and outpatient contacts to specialized psychiatric treatment facilities. While information of inpatient treatment was available throughout the entirety of the study period data on outpatient contact were added to the national Danish registers from 1995 and onwards. Some women from the comparison groups of women without mental disorders (mothers and non-mothers) might have received treatment for mild-moderate mental disorders at their general practitioners without treatment being registered in the Danish Psychiatric Central Register and this information would therefore not be captured in our data. However such

possible misclassification would lead to an underestimation of the risk of self harm and suicide, rather than dilute our findings.

As self-harm is often stigmatized all uncertainties regarding the correct coding of self-harm as a deliberate act versus an accident cannot be ruled out completely. We applied a Danish developed algorithm for defining self-harm (Gasse et al., 2018) which includes a more general spectrum of self-harm and could capture accidental injuries (e.g. overdose).

However this potential misclassification bias would again lead to an underestimation of the prevalence of later suicide, as some deaths recorded as being accidental may have in fact been suicides, rather than dilute our findings.

The women included in this study were born from 1963 and followed until the year 2016. As a consequence, our cohort mainly consisting of younger women, illustrated with 17,947,653 (74.6%) of the person-years at risk within the age groups under 35 years (Table 1). This age distribution potentially limits generalizability of our results to older mothers. However, as it has been shown that self-harming behaviour is especially prominent among younger individuals (Abdelraheem et al., 2019) we do believe that our study population is suitable for answering the study questions proposed.

We adjusted for possible confounding from age, family history of mental disorders and family history of suicidal behavior from both parental self-harm and/or suicide in our analyses, however as in any observational study we cannot rule out possible residual confounding.

## **Conclusion**

Women with the most severe postpartum mental disorders registered with a specialized psychiatric treatment have an increased risk of self-harm following their initial postpartum

diagnosis when compared to mothers without a history of psychiatric diagnosis and treatment.

However, among all groups of psychiatric patients (both mothers and childless women with alternate onset of mental disorders) women with postpartum mental disorders have the lowest risk of self-harm.

Nevertheless, particular concern should be focused on women with postpartum mental disorders with a record of self-harm, as this group represents a clinical cohort with a significantly increased risk of subsequent suicide.

| Yes   | 256,265              | 663                    |
| No  | 23,797,276           | 36,668                 |

1: Women with any first psychiatric inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to her first child.

2: Women with a record of childbirth but without any record of a psychiatric inpatient or outpatient contact.

3: Women with a record of childbirth and an inpatient or outpatient contact to a psychiatric facility outside the 90-day postpartum period.

4: Women without any record of childbirth but with a first inpatient or outpatient contact to a psychiatric facility.

5: Women without any record of childbirth and without any record of an inpatient or outpatient contact to a psychiatric facility.

6: At least one mother and/or farther with a record of inpatient or outpatient psychiatric treatment.

7: At least one mother and/or farther with a hospital registered episode of self-harm

8: At least one mother and/or farther dying from suicide.

Table 2. Adjusted hazard ratios for self-harm in women with postpartum mental disorders and four comparison groups

|  | Hazard ratio (HR) <sup>1</sup> | 95%CI     |
|--|--------------------------------|-----------|
| Women with postpartum mental disorders <sup>2</sup>                                | 6.2                            | 4.9-8.0   |
| Mothers without mental disorders <sup>3</sup>                                      | 1                              | reference |
|  |                                |           |
| Mothers with mental disorders diagnosed outside the postpartum period <sup>4</sup> | 10.1                           | 9.6-10.5  |
| Childless women <i>with</i> mental disorders <sup>5</sup>                          | 9.3                            | 8.9-9.7   |
| Childless women <i>without</i> mental disorders <sup>6</sup>                       | 0.9                            | 0.9-1.0   |

1: Adjusted for calendar time and family history of mental illness, family history of self-harm and family history of suicide.

2: Women with any first psychiatric inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to her first child.

3: Women with a record of childbirth but without any record of a psychiatric inpatient or outpatient contact.

4: Women with a record of childbirth and an inpatient or outpatient contact to a psychiatric facility outside the 90-day postpartum period.

5: Women without any record of childbirth but with a first inpatient or outpatient contact to a psychiatric facility.

6: Women without any record of childbirth and without any record of an inpatient or outpatient contact to a psychiatric facility.

Table 3. Short-term vs. long-term risk of self-harm among women with postpartum mental disorders and four comparison groups

|  | Short-time risk of self-harm |                |                              |                       | Long-term risk of self-harm |                |                             |                      |
|--|------------------------------|----------------|------------------------------|-----------------------|-----------------------------|----------------|-----------------------------|----------------------|
|  | Person years                 | N <sup>1</sup> | Short-term risk <sup>2</sup> | 95%CI short-term risk | Person years                | N <sup>3</sup> | Long-term risk <sup>2</sup> | 95%CI long-term risk |
| Women with postpartum mental disorders <sup>4</sup>                                  | 1,499                        | 17             | 13.5                         | 8.4-21.7              | 15,597                      | 47             | 5.2                         | 3.9-6.9              |
| Mothers without mental disorders (reference) <sup>5</sup>                            |                              |                |                              |                       | 8,919,834                   | 4,950          | 1                           | (reference)          |
| Mothers with diagnosis of mental disorder outside the postpartum period <sup>6</sup> | 45,752                       | 904            | 30.4                         | 28.3-32.6             | 629,253                     | 3,135          | 8.4                         | 8.0-8.7              |
| Childless women <i>with</i> mental disorders <sup>7</sup>                            | 91,258                       | 3,318          | 20.5                         | 19.4-21.6             | 660,461                     | 6,519          | 7.7                         | 7.4-8.1              |
| Childless women <i>without</i> mental disorders <sup>8</sup>                         |                              |                |                              |                       | 13,689,887                  | 18,441         | 1.0                         | 0.9-1.0              |

1: Number of women with first record of self-harm within the first 12 months after first psychiatric inpatient or outpatient contact.

2: Adjusted for age, calendar time, family history of mental illness, family history of self-harm and family history of suicide.

3: Number of women with first record of self-harm after 12 months following first psychiatric inpatient or outpatient contact.

4: Women with any first psychiatric inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to her first child.

5: Women with a record of childbirth but without any record of a psychiatric inpatient or outpatient contact.

6: Women with a record of childbirth and an inpatient or outpatient contact to a psychiatric facility outside the 90-day postpartum period.

7: Women without any record of childbirth but with a first inpatient or outpatient contact to a psychiatric facility.

8: Women without any record of childbirth and without any record of an inpatient or outpatient contact to a psychiatric facility.

Table 4. Survival analysis showing the risk of suicide among the women with at least one hospital registered episode of self-harm in five comparison groups.

|   | Person-years<br>at risk | N <sup>1</sup> | Hazard ratio <sup>2</sup> | 95%CI     |
|---|-------------------------|----------------|---------------------------|-----------|
| Women with postpartum psychiatric disorders <sup>3</sup>                      | 604                     | 5              | 8.7                       | 3.5-21.7  |
| Mothers without psychiatric diagnosis (reference) <sup>4</sup>                | 59,913                  | 61             | 1                         | reference |
|   |                         |                |                           |           |
| Mothers with psychiatric diagnosis outside the postpartum period <sup>5</sup> | 35,752                  | 90             | 2.7                       | 1.9-3.7   |
| Childless women <i>with</i> psychiatric diagnosis <sup>6</sup>                | 92,573                  | 185            | 2.8                       | 2.1-3.8   |
| Childless women <i>without</i> psychiatric diagnosis <sup>7</sup>             | 264,007                 | 165            | 0.7                       | 0.5-0.9   |

1: Women with at least one hospital record of self-harm who later died by completed suicide.

2: Hazard ratio adjusted for age, calendar time, family history of mental illness, family history of self-harm and family history of suicide.

3: Women with any first psychiatric inpatient or outpatient contact to a psychiatric facility within 90 days after giving birth to her first child.

4: Women with a record of childbirth but without any record of a psychiatric inpatient or outpatient contact.

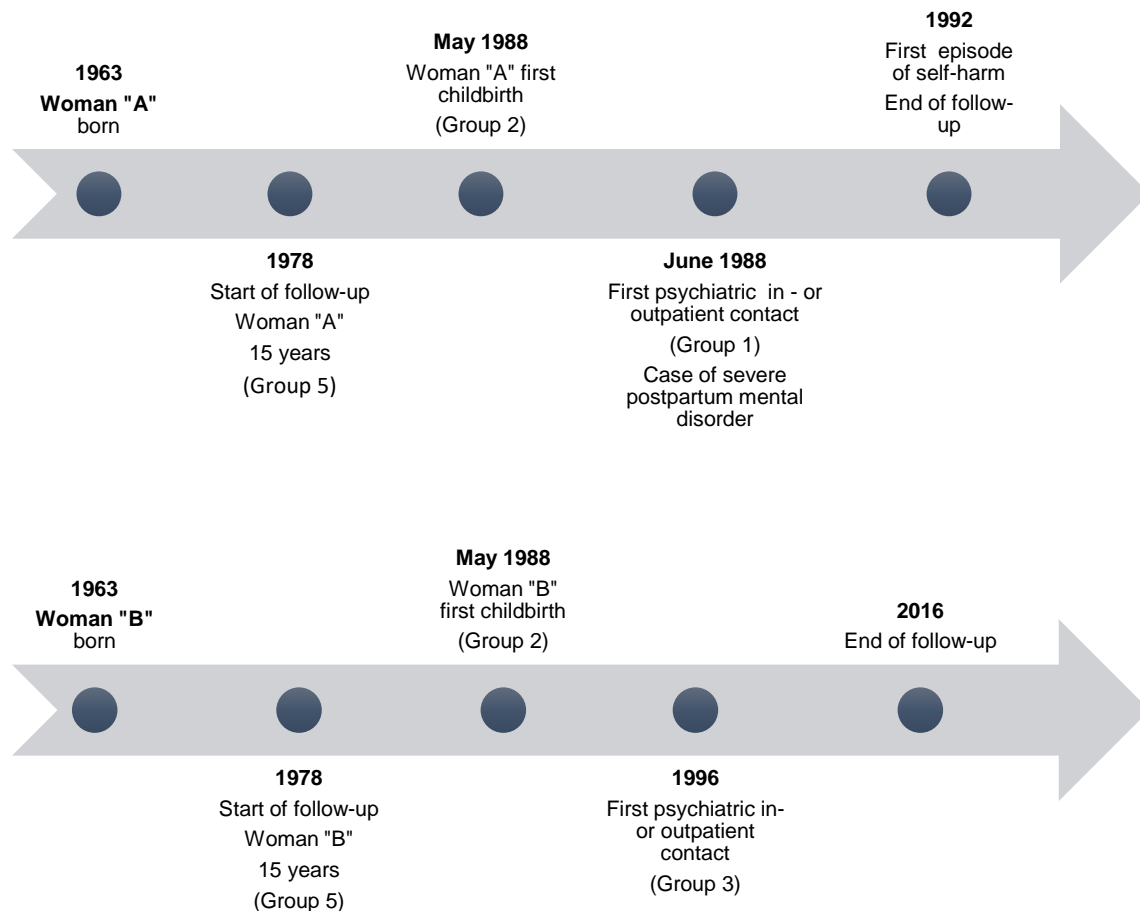

5: Women with a record of childbirth and an inpatient or outpatient contact to a psychiatric facility outside the 90-day postpartum period.

6: Women without any record of childbirth but with a first inpatient or outpatient contact to a psychiatric facility.

7: Women without any record of childbirth and without any record of an inpatient or outpatient contact to a psychiatric facility.

# Appendix 1.

Consider the following example: Woman "A" enters the cohort at age 15 years with no record of psychiatric contact or childbirths (group 5). She will contribute person-years at risk in this group, until she gives birth to her first child (group 2). Within the first 90 days after childbirth, she is registered with her first psychiatric contact (group 1). She will remain in this category and contribute person-years at risk until end of follow-up. In comparison, Woman "B" has her first contact to a psychiatric facility more than 90 days after giving birth to her child, and she consequently contributes to person-time in group 3 from the day of her recorded psychiatric diagnosis. She will remain in group 3 throughout the entirety of the follow-up period.

**Appendix 2.** Adjusted hazard ratios for self-harm in women with **postpartum mental disorders with onset within 0-6 months** postpartum and four comparison groups

|  | Hazard ratio (HR) <sup>1</sup> | 95%CI     |
|--|--------------------------------|-----------|
| Women with postpartum mental disorders <sup>2</sup>                                | 6.6                            | 5.4-7.9   |
| Mothers without mental disorders <sup>3</sup>                                      | 1                              | reference |
|  |                                |           |
| Mothers with mental disorders diagnosed outside the postpartum period <sup>4</sup> | 9.6                            | 9.2-10.0  |
| Childless women <i>with</i> mental disorders <sup>5</sup>                          | 8.6                            | 8.2-9.0   |
| Childless women <i>without</i> mental disorders <sup>6</sup>                       | 0.9                            | 0.8-0.9   |

1: Adjusted for calendar time and family history of mental illness, family history of self-harm and family history of suicide.

2: Women with any first psychiatric inpatient or outpatient contact to a psychiatric facility within 180 days after giving birth to her first child.

3: Women with a record of childbirth but without any record of a psychiatric inpatient or outpatient contact.

4: Women with a record of childbirth and an inpatient or outpatient contact to a psychiatric facility outside the 180-day postpartum period.

5: Women without any record of childbirth but with a first inpatient or outpatient contact to a psychiatric facility.

6: Women without any record of childbirth and without any record of an inpatient or outpatient contact to a psychiatric facility.
